Software Packages for Deep Learning

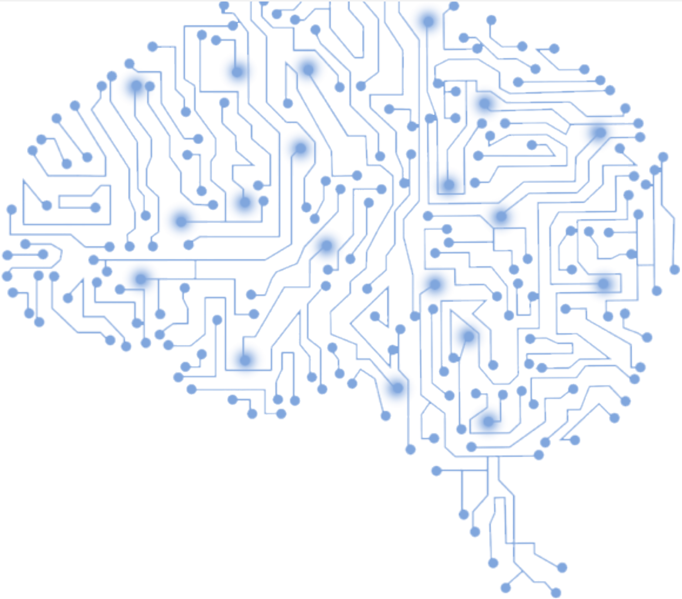
Chensong Zhang

with Zheng Li and Ronghong Fan

DL Seminar — April 27, 2017

Outline

- Introduction
- Comparison
- Python
- TensorFlow
- MXNet
- Torch
- Caffe



§1. Introduction

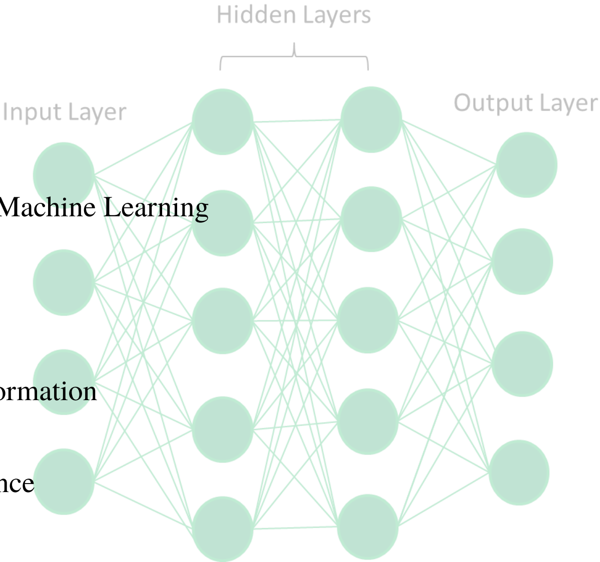
1 Machine Learning

2 Software Packages for Machine Learning

3 Deep Learning

4 DL Engines: Basic Information

5 DL Engines: Performance



Machine Learning

Why ML now?

- Unlike traditional numerical simulation, "ML gives computers the ability to learn without being explicitly programmed" [Samuel 1959]
- As a research field, ML explores the study and construction of algorithms that can learn from and make predictions on data
- Fourth paradigm, big data, artificial intelligence, Internet of things, ...

General Tasks of ML:

- Classification: Inputs are divided into two or more classes, and the learner must produce a model that assigns unseen inputs to one or more (multi-label classification) of these classes
- Clustering: Inputs are divided into groups. Unlike in classification, the groups are not known beforehand, making this typically an unsupervised task
- Regression: Similar to classification, but the outputs are continuous
- Density estimation, dimensionality reduction, ...

I. Goodfellow, Y. Bengio, and A. Courville, https://github.com/exacity/deeplearningbook-chinese

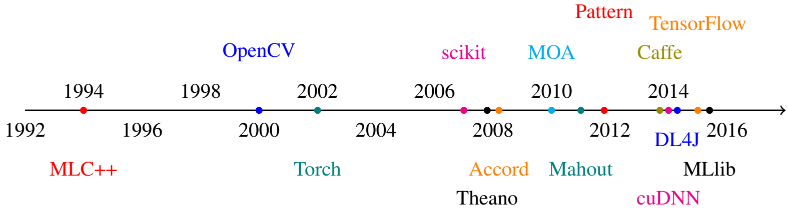
Software Packages for Machine Learning

What is the purpose?

- Solving problems from practical applications (user interface)
- Developing algorithms and optimizing implementation (development)
- Theoretical analysis for machine learning

What do we want for a ML package?

- Easy for new tasks and new network structures (less steep learning curve)
- Easy for debugging (with good support and large community)
- Performance and scalability



Tour of TensorFlow, by Peter Goldsborough, arXiv, 2016

Deep Learning

Deep Learning has been introduced with the objective of moving ML closer to one of its original goals—AI. The main motivations includes:

- Insufficient depth can hurt
- The brain has a deep architecture
- Cognitive processes seem deep

Pros:

- conceptually simple
- nonlinear
- highly flexible and configurable
- learned features can be extracted
- can be fine-tuned with more data
- efficient for multi-class problems
- world-class at pattern recognition

Cons:

- hard to interpret
- theory not well understood
- slow to train and score
- overfits, needs regularization
- more parameters
- inefficient for categorical variables
- data hungry, learns slowly

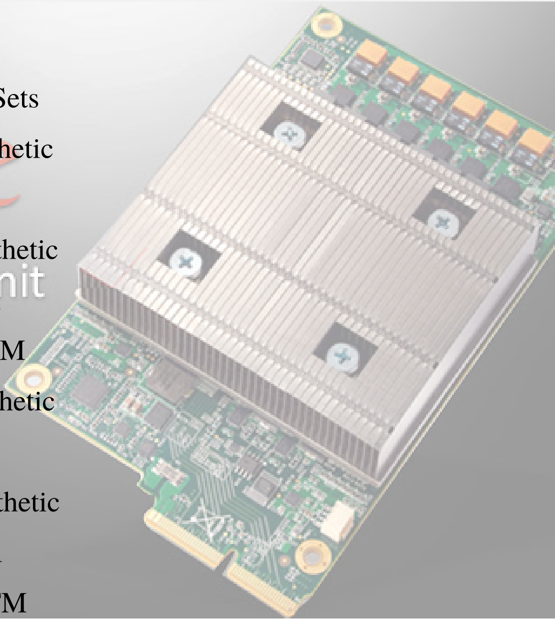
§2. Comparison



Hardware Platforms

- Use one quad-core desktop CPU (i.e., Intel i7-3820 CPU @ 3.60GHz) and two 8-core server-grade CPUs (i.e., Intel Xeon CPU E5-2630 v3 @ 2.40GHz)
- Use two generations of GPU cards, GTX 1080 @ 1607MHz with Pascal architecture, and Telsa K80 @ 562MHz with Kepler architecture

Computational Unit	Cores	Memory	OS	CUDA
Intel CPU i7-3820	4	64 GB	Ubuntu 14.04	-
Intel CPU E5-2630x2	16	128 GB	CentOS 7.2	-
GTX 980	2048	4 GB	Ubuntu 14.04	8.0
GTX 1080	2560	8 GB	Ubuntu 14.04	8.0
Telsa K80 GK210	2496	12 GB	CentOS 7.2	8.0

Benchmarking State-of-the-Art Deep Learning Software Tools, by S.-H. Shi, et al., arXiv, 2017

Neural Networks and Data Sets

- A large fully-connected neural network (FCN-S) with around 55 million parameters is used to evaluate the performance of FCN
- The classical AlexNet (AlexNet-S) is used as an representative of CNN
- A smaller FCN (FCN-R) is constructed for MNIST data set
- An AlexNet (AlexNet-R) architecture is used for Cifar10 data set
- For RNNs, considering that the main computation complexity is related to the length of input sequence, 2 LSTM layers are selected for testing, with input length of 32.

Networks		Input	Output	Layers	Parameters
FCN	FCN-S	26752	26752	5	~55 millions
FCN	FCN-R	784	10	5	~31 millions
CNN	AlexNet-S	150528	1000	4	~61 millions
CNN	AlexNet-R	3072	10	4	~81 thousands
RNN	LSTM	10000	10000	2	~13 millions

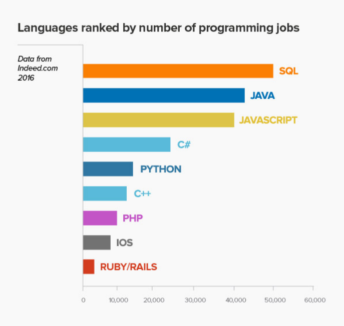
§3. Python

Python: A general-purpose programming language

- Created by Guido van Rossum in 1989 and first released in 1991
- Named after “the Monty Python” (British comedy group)
- An interpreted language—simple, clear, and readable
- Python has many excellent packages for machine learning
- The language of choice in introductory programming courses



Feb 2017	Change	Programming language	Share	Trends
1		Java	22.6 %	-1.3 %
2		Python	14.7 %	+2.8 %
3		PHP	9.4 %	-1.2 %
4		C#	8.3 %	-0.3 %
5	↑↑	Javascript	7.7 %	+0.4 %
6		C	7.0 %	-0.2 %
7	↓↓	C++	6.9 %	-0.6 %
8		Objective-C	4.2 %	-0.6 %
9	↑	R	3.4 %	+0.4 %
10	↓	Swift	2.9 %	+0.1 %

Python for Scientific Computing

Why Python for scientific computing?

- Dynamic data types and automatic memory management
- Full modularity, supporting hierarchical packages
- Strong introspection capabilities[1]
- Exception-based error handling

Why consider such a slow language for simulation?

- Good for proof-of-concept prototyping
- Implementation time versus execution time
- Code readability and maintenance — short code, fewer bugs
- Well-written Python code is “fast enough” for most computational tasks
- Time critical parts executed through compiled language or available packages

[1] Code introspection is the ability to examine classes, functions and keywords to know what they are, what they do and what they know. Python provides several functions and utilities for code introspection, like dir(), help(), type().

Built-in Data Structures

Numeric types: int, float, complex

```
b=1L     # long int
c=0xf    # int (hex format)
d=010    # int (octal format)
e=1.0    # float
f=1+2j   # complex
```

Sequence types: list, tuple, str, dict

```
t=(3.14, True, 'Yes', [1], (0xf,))                  # tuple example
l=[3.14, True, 'Yes', [1], (1L, 0xf)] + [None]*3    # list example
s='Hello' + ", " + 'world!'                         # str example 1
s=("Hello, " "world!")                              # str example 2
d={1: 'int', 'pi': 3.14}                            # dict example
s="Python"; s.find('thon')                          # find substring
```

Formatted output

```
print('%(lang)s has %(num)02d quote types.' %{"lang":"Python", "num":3})
```

User defined functions[2][3]

```
def square(x):
    return x*x
```

[2] Function overhead is high. Not to call a function repeatedly; Using aggregation instead.

[3] Python always passes (the value of) the reference to the object to the function.

Control Flow

If-then-else

```
a = 1
if a > 0:
    print "a is positive"
elif a=0:
    print "a is zero"
else:
    print "a is negative"
```

For loop

```
# loop from 0 to 9
for i in range(10):
    print i

# loop over the list named by oldlist
newlist = [s.upper() for s in oldlist]

a = range(5)  # create a new list a
b = a         # b points to the list a
c = [item for item in a]   # copy list a to a new list
```

While loop

```
sum = 0; i = 0
while i < 10:
    sum += i
    i += 1
```

Modules

- This way will only introduce the name ‘math’ into the name space in which the import command was issued. The names within the math module will not appear in the enclosing namespace: they must be accessed through the name math.

```
import math
math.sin(3.14)
```

- This way does not introduce the name math into the current namespace. It does introduce all public names of the math module into the current namespace.

```
from math import *
sin(3.14)
```

- This will only import the sin function from math module and introduce the name sin into the current namespace, but it will not introduce the name math into the current namespace, directly use

```
from math import sin
sin(3.14)
```

- Make it as local as possible to avoid import overhead; But avoid calling it repeatedly; If possible, avoid it!

Additional Comments

1. In Python, everything (including functions, modules, and files) are objects. A variable is created through assignment:

```
x = y = z = 0.1
```

2. help() is a function which gives information about the object. For example,

```
help('modules')        # generate a list of all modules that can be imported
help('modules time')   # generate a list of modules with 'time' in description
```

3. Use a profiler to find optimization possibilities

```
import profile         # cProfile is now recommended
profile.run('main()')
```

4. Some useful and important packages
   - NumPy: for scientific computing
   - Matplotlib/Pylab: for visualising data
   - SciPy: providing lots of numerical algorithms
   - SymPy: for symbolic mathematics

http://www.pythontutor.com

§4. TensorFlow

Programming Interface

- Graph: In TensorFlow, machine learning algorithms are represented as computational graph. A computational or data flow graph is a form of directed graph where vertices or nodes describe operations, while edges represent data flowing between these operations.
- Operation: An operation may represent a mathematical equation, a variable or constant, a control flow directive, a file I/O operation or even a network communication port.
- Tensor: A tensor is a multi-dimensional collection of homogeneous values with a fixed, static type.
- Variable: Variables can be described as persistent, mutable handles to in-memory buffers storing tensors.
- Session: In TensorFlow the execution of operations and evaluation of tensors may only be preformed in a special environment called session.

Computational Graph

```python
import tensorflow as tf

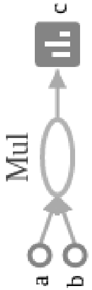
graph = tf.Graph()

with graph.as_default():
    # Define two constants
    a = tf.constant(1.0)
    b = tf.constant(2.0)

    # Define an operation node: c = a * b
    c = tf.multiply(a, b)
    # Add scalar summary to operation node
    tf.summary.scalar('c', c)

    # Merge all the summaries and write to ./board
    merged = tf.summary.merge_all()
    writer = tf.summary.FileWriter('./board', graph)

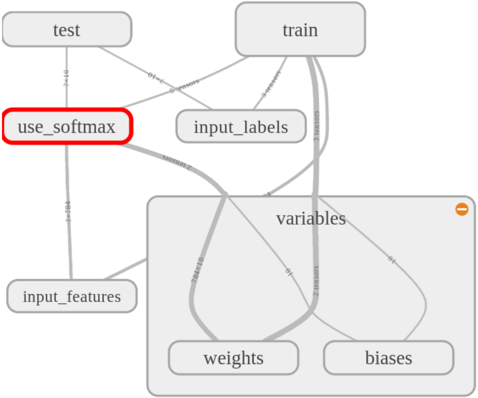
with tf.Session(graph=graph):
    # Write data to ./board
    writer.add_summary(merged.eval())
```



Visualization: TensorBoard

Computation graphs are powerful but complicated

- thousands of nodes or more
- network is deep
- graph visualization tool TensorBoard is helpful



Example: SoftMax in TF

```
import tensorflow as tf

# Import training and test data
import tensorflow.examples.tutorials.mnist.input_data as input_data
mnist = input_data.read_data_sets("MNIST_data/", one_hot=True)

# Create a new TensorFlow graph
graph = tf.Graph()
with graph.as_default():
    # Nodes or entire subgraphs can be grouped into one visual block for tensorboard
    with tf.name_scope('input_features'):
        # Placeholder for input variables (None = variable dimension)
        x = tf.placeholder(tf.float32, shape=[None, 784], name='input_x')

    with tf.name_scope('input_labels'):
        # Placeholder for labels
        y_ = tf.placeholder(tf.float32, shape=[None, 10], name='labels')

    with tf.name_scope('variables'):
        W = tf.Variable(tf.zeros([784, 10]), name='weights')
        # Track tensor distributions over time for tensorboard
        tf.summary.histogram('WEIGHTS', W)
        b = tf.Variable(tf.zeros([10]), name='biases')
        tf.summary.histogram('BIASES', b)

    with tf.name_scope('use_softmax'):
        # Apply softmax regression model to the input data and get prediction y
        y = tf.nn.softmax(tf.matmul(x, W) + b)
```

Example: SoftMax in TF (Cont)

```
    with tf.name_scope('train'):
        # Compute the cross entropy of real label y_ and prediction labe y
        cross_entropy = -tf.reduce_sum(y_*tf.log(y))
        # Create a gradient-descent optimizer with learning rate = 0.01
        train_step = tf.train.GradientDescentOptimizer(0.01).minimize(cross_entropy)

    with tf.name_scope('test'):
        correct_prediction = tf.equal(tf.argmax(y,1), tf.argmax(y_,1))
        accuracy = tf.reduce_mean(tf.cast(correct_prediction, "float"))
        # Track tensor values over time for tensorboard
        tf.summary.scalar('Accuracy', accuracy)

    # Merge all the summaries and write to ./board
    merged = tf.summary.merge_all()
    writer = tf.summary.FileWriter('./board', graph)

with tf.Session(graph=graph) as sess:
    # Initialize all variables
    tf.global_variables_initializer().run()

    for step in range(1000):
        if (step%10) == 0:
            # Feed test data to compute accuarcy
            feed = {x: mnist.test.images, y_: mnist.test.labels}
            _, acc = sess.run([merged, accuracy], feed_dict=feed)
            print('Accuracy at %s step: %s' %(step, acc))
        else:
            # Feed training data to train the model
            batch_x, batch_y = mnist.train.next_batch(100)
            sess.run(train_step, feed_dict={x: batch_x, y_: batch_y})
            writer.add_summary(merged.eval(feed_dict={x:batch_x, y_:batch}),
                               global_step=step)
```

§5. MXNet

Programming Interface

1. Support many scope applications (e.g. computer vision, natural language processing, speech recognition, unsupervised machine learning, support embedded APIs, visualization)
2. Mixed programming style: imperative and declarative
   - Data parallelism with multi-devices: Better scalability than TensorFlow, reportedly
   - Support many different front-end, including JavaScript (so it be run on web browsers as well)
   - Provide intermediate-level and high-level interface modules
   - Provide abundant IO functions
3. Fully compatible with Torch: modules and operators
4. Support building neural network graphs
   - Call mx.viz.plot_network( )
5. Not well documented

Example: SoftMax in MXNet

```
import mxnet
import mxnet.symbol as sym
import numpy as np
import numpy.random as random
import time
from minpy.core import function
from minpy.core import grad_and_loss

# define softmax symbol
x_shape = (num_samples, num_classes)
label_shape = (num_samplesm,)
softmax_symbol = sym.SoftmaxOutput(data=sym.Variable('x'),
                                   name='softmax', grad_scale=1.0/num_samples)

# convert MXNet symbol into a callable function
# corresponding gradient function
softmax = function(softmax_symbol, [('x', x_shape), ('softmax_label', label_shape)])

# make softmax_label;
# MXNet's softmax operator does not use one-of-many label format
softmax_label = np.argmax(label, axis=1)

# Redefine loss function using softmax as one operator
def train_loss(w, x):
    y = np.dot(x, w)
    prob = softmax(x=y, softmax_label=softmax_label)
    loss = -np.sum(label * np.log(prob)) / num_samples
    return loss
```

Example: SoftMax in MXNet (Cont)

```
# Initialize weight matrix (again)
weight = random.randn(num_features, num_classes)

# Calculate gradient function automatically
grad_function = grad_and_loss(train_loss)

# Now training it for 100 iterations
start_time = time.time()
for i in range(100):
    dw, loss = grad_function(weight, data)
    if i % 10 == 0:
        print 'Iter {}, training loss {}'.format(i, loss)
    weight -= 0.1 * dw

print 'Training time: {}s'.format(time.time() - start_time)
```

§6. Torch

Programming Interface

1. Wide range of applications
   - Speech, image and video applications
   - Large-scale machine-learning applications
2. Fastest scripting language Lua is used
3. Portable to any platform
   - Torch can run on iPhone with no modification to scripts
   - Embeddable, with ports to iOS, Android and FPGA backends
4. Easy extensibility
   - Easy to integrate any library into Torch

Example: Two-Layer Network

```
import torch
from torch.autograd import Variable

# N is batch size; D_in is input dimension;
# H is hidden dimension; D_out is output dimension.
N, D_in, H, D_out = 64, 1000, 100, 10

# Create random Tensors to hold inputs and outputs, and wrap them in Variables.
x = Variable(torch.randn(N, D_in))
y = Variable(torch.randn(N, D_out), requires_grad=False)

# Use the nn package to define our model as a sequence of layers.
model = torch.nn.Sequential( torch.nn.Linear(D_in, H),
                             torch.nn.ReLU(),
                             torch.nn.Linear(H, D_out) )

# The nn package also contains definitions of popular loss functions;
loss_fn = torch.nn.MSELoss(size_average=False)

learning_rate = 1e-4

for t in range(500):
    # Forward pass: compute predicted y by passing x to the model.
    y_pred = model(x)
    # Compute and print loss.
    loss = loss_fn(y_pred, y)
    print(t, loss.data[0])
    # Zero the gradients before running the backward pass
    model.zero_grad()
```

Example: Two-Layer Network (Cont)

```
    # Backward pass: compute gradient of the loss
    loss.backward()

    # Update the weights using gradient descent
    for param in model.parameters():
        param.data -= learning_rate * param.grad.data
    end
end
```

https://github.com/jcjohnson/pytorch-examples

Example: Linear Regression in Lua

```lua
require 'torch'
require 'optim'
require 'nn'

# write the loss to a text file and read from there to plot it as training proceeds
logger = optim.Logger('loss_log.txt')

# input data
data = torch.Tensor{{40,  6,  4},{44, 10,  4},{46, 12,  5},
{48, 14,  7},{52, 16,  9},{58, 18, 12},{60, 22, 14},
{68, 24, 20},{74, 26, 21},{80, 32, 24}}

# define the container
model = nn.Sequential()
ninputs = 2; noutputs = 1

# define the only module
model:add(nn.Linear(ninputs, noutputs))

# Define a loss function
criterion = nn.MSECriterion()

# retrieve its trainable parameters
x, dl_dx = model:getParameters()

# compute loss function and its gradient
feval = function(x_new)
   # set x to x_new, if differnt
   if x ~= x_new then
      x:copy(x_new)
   end
```

Example: Linear Regression in Lua (Cont)

```lua
   # select a new training sample
   _nidx_ = (_nidx_ or 0) + 1
   if _nidx_ > (#data)[1] then _nidx_ = 1 end

   local sample = data[_nidx_]
   local target = sample[{ {1} }]
   local inputs = sample[{ {2,3} }]

   # reset gradients
   dl_dx:zero()

   # evaluate the loss function and its derivative wrt x
   local loss_x = criterion:forward(model:forward(inputs), target)
   model:backward(inputs, criterion:backward(model.output, target))

   # return loss(x) and dloss/dx
   return loss_x, dl_dx
end

# define SGD
sgd_params = {
   learningRate = 1e-3,
   learningRateDecay = 1e-4,
   weightDecay = 0,
   momentum = 0
}

# we cycle 10,000 times over our training data
for i = 1,1e4 do
   #this variable is used to estimate the average loss
   current_loss = 0
```

Example: Linear Regression in Lua (Cont)

```lua
    #an epoch is a full loop over our training data
    for i = 1,(#data)[1] do
        # return new x and value of the loss functions
        _,fs = optim.sgd(feval,x,sgd_params)
        # update loss
        current_loss = current_loss + fs[1]
    end

    # report average error on epoch
    current_loss = current_loss / (#data)[1]
    print('current loss = ' .. current_loss)

    logger:add{['training error'] = current_loss}
    logger:style{['training error'] = '-'}
    logger:plot()
end

# Test the trained model
text = {40.32, 42.92, 45.33, 48.85, 52.37, 57, 61.82, 69.78, 72.19, 79.42}

for i = 1,(#data)[1] do
    local myPrediction = model:forward(data[i][{{2,3}}])
    print(string.format("%2d %6.2f %6.2f", i, myPrediction[1], text[i]))
end
```

§7. Caffe

Caffe

Deep learning framework by BAIR

Programming Interface

1. Mainly focus on (and well suited for) CNN and image recognition
2. Expressive architecture
   - Define models and optimization by configuration without hard-coding
   - With protocol tool to define parameters for nets and solvers . . .
3. Not well documented

Example: Image Classification

```
import caffe
import matplotlib.pyplot as plt

# paste your image URL here
my_image_url = "https://wikipedia/Orang_Utan/2C_Malaysia.JPG"
!wget -O image.jpg $my_image_url

# transform it and copy it into the net
image = caffe.io.load_image('image.jpg')
caffe.net.blobs['data'].data[...]=transformer.preprocess('data',image)

# perform classification
caffe.net.forward()

# obtain the output probabilities
output_prob = net.blobs['prob'].data[0]

# sort top five predictions from softmax output
top_inds = output_prob.argsort()[::-1][:5]

#
plt.imshow(image)

#
print 'probabilities and labels:'
zip(output_prob[top_inds], labels[top_inds])
```

Example: Extend Layers

```
import caffe
import numpy as np

class EuclideanLoss(caffe.layer):
    def setup(self, bottom, top):
        #check input pair
        if len(bottom) != 2:
            raise Exception("Need two inputs to compute distance")

    def reshape(self, bottom, top):
        #check input dimensions match
        if bottom[0].count != bottom[1].count:
            raise Exception("Inputs must have the same dimension")
        #difference in shape of inputs
        self.diff = np.zeros_like(bottom[0].data, dtype=np.float32)
        # loss output is scalar
        top[0].reshape(1)

    def forward(self, bottom, top):
        self.diff[...] = bottom[0].data - bottom[1].data
        top[0].data[...] = np.sum(self.diff**2)/bottom[0].num/2.

    def backward(self, top, propagate_down, bottom):
        for i in range(2):
            if not propagate_down[i]:
                continue
            if i == 0:
                sign = 1
            else:
                sign = -1
```

Example: Extend Layers (Cont)

```
            bottom[i].diff[...] = sign.self.diff / bottom[1].num
```

Define a class in Python to extend Layer

```
layer{
    type: "Python"
    python_param {
        module: "laylers"
        layer: "EuclideanLoss"
    }
}
```
